

What we knew till 2017

- RNNs are slow at inference: Sequential nature
- Gradients and history are tricky to handle for long sequences.
- Encoder - Decoder architecture is useful.
- Multi-step learning is better
- Residual connections are helpful: Vision domain
ResNet
- Core idea of Vaswani et al.
Why not combine all good things and get rid of the problematic parts?

Core Concepts of Transformer

- Self attention
- Multiple heads
- Masked attention
- Encoder-Decoder attention
- Residual connections
- Positional embeddings

High Level Architecture

Let us make encoding and decoding
multi step process

• All E_s are identical. All D_s are identical.

RNN:

~~No~~ Recurrence (on input)

Transformer

Add position embedding
to keep track of order

Do NOT forget that

Encoder Architecture

Residual Connection + Normalization
FFNN

Residual Connection + Normalization
Self Attention

सुनो सबकी, करो मन की

Old is gold (perhaps)

अति सर्वत्र वर्जयेत्।

Self Attention Block

Now each token has three representation

$$q_i = x_i W_Q \quad k_i = x_i W_K \quad v_i = x_i W_V$$

Output representation

$$Z_i = \sum_{k=1}^{512} w_{ik} v_k$$

x_i : row of X
 q_i : Q
 k_i : K
 v_i : V

$$w_{ik} \propto q_i \cdot k_k$$

$$\text{Attention}(Q K V) = \text{Softmax} \left(\frac{Q K^T}{\sqrt{d_k}} \right) V$$

Scaling for stability

There are multiple attention heads

- Final output from self-attention block

$$\text{Multihead}(Q, K, V) =$$

$$\text{Concat}(\text{Head}_1, \text{Head}_2, \dots, \text{Head}_n) \cdot W^o$$

$$W^o: (h \times d_v) \times d_{\text{model}}$$

Residual Connection

• Deal with Vanishing gradient problem

$$\frac{\partial E}{\partial w_1} = \frac{\partial E}{\partial w_n} \cdot \frac{\partial w_n}{\partial w_{n-1}} \cdot \dots \cdot \frac{\partial w_2}{\partial w_1}$$

Vanishing gradient
↙ ↘
Weight Activation
magnitude gradient

- Self attention might output 2 as zeros.
- Sometimes old representation still carries the value.
- Residual connection is the hedge against wrong or bad transformation.

Layer Norm

$x_3^0, x_3^1, \dots, x_3^{512}$: Vector for a single token

$$x_4^i = \frac{x_3^i - \mu}{\sqrt{\sigma^2 + \epsilon}}$$

mean across all dimensions of x_3

avoid division by zero

variance of x_3 across all dimensions

$$x_5^i = \gamma_a^i x_4^i + \beta_a^i$$

Learnable parameters

- Numerical Stability
- Avoid exploding and vanishing gradients problem
- Mean zero, allows to use both sides of activation
- Variance one, keeps magnitude in check

Feed Forward Layer

- Single hidden layer with ReLU activation

$$x_6 = (\text{ReLU}(x_5 W_1 + b_1)) W_2 + b_2$$

You can use any other activation function

- Large hidden size: 512 $\xrightarrow{\text{dff}}$ 2048 $\rightarrow$ 512
- One more residual connection

$$x_7 = x_5 + x_6$$

- One more layer norm

$$x_8^i = \frac{x_7^i - \mu}{\sqrt{\sigma^2 + \epsilon}}$$

$$x_9^i = \gamma_b^i x_8^i + \beta_b^i$$

Learnable parameters

Without Position Encoding, it's a Bag of Words

$$PE(pos, 2i) = \sin\left(\frac{pos}{10000^{(2i/d_{model})}}\right)$$

$$PE(pos, 2i+1) = \cos\left(\downarrow\right)$$

- What happens if same word appears at multiple positions?
- $x_1 = x_0 + PE(pos)$
- $PE(pos)$ is a distinct vector for each position
- Position encoding is added only at the first encoder. Rest of the encoders do not use it explicitly.

Encoder Stack has multiple encoders

- Multi Step transformation has higher chance of being successful.
- Let us do the encoder side parameter count
 $\underline{V}$ = vocab size $\underline{d_{model}}$ = Model dimensionality
 $\underline{n}$ = Number of tokens $\underline{h}$ = Number of heads

$$\underline{\underline{d_k}} = \frac{d_{model}}{h} \quad \underline{\underline{d_{ff}}} = FFN \text{ hidden layer size}$$

Base model

$$V = 37K \quad d_{model} = 512$$

$$\text{Total} \approx 3.15M \text{ per encoder}$$

$$W_q W_k W_v W_o : 4 \times d_{model}^2 \approx 1.04M$$

$$+ 4 \times d_{model} \text{ bias} \approx 2K$$

$$\cdot FFN: (512 \times 2048) + (512 \times 2048) + \text{biases} \approx 2.09M$$

$$\cdot \text{Layer Norm: } 2 \times 2 \times d_{model} \approx 2K$$

Decoder Work Sequentially Like an RNN during the inference

- Using previously predicted sequence, predict next token

- Assume first fake input $\langle \text{SOS} \rangle$

- Teacher forcing during training

- Translation task

I went to school $\rightarrow$ मैं स्कूल गया था

- At Decoder

$\langle \text{SOS} \rangle \rightarrow$ मैं

$\langle \text{SOS} \rangle$ मैं $\rightarrow$ स्कूल

$\langle \text{SOS} \rangle$ मैं स्कूल $\rightarrow$ गया।

$\langle \text{SOS} \rangle$ मैं स्कूल गया $\rightarrow$ था

$\langle \text{SOS} \rangle$ मैं स्कूल गया था $\rightarrow \langle \text{EOS} \rangle$

During training decoder learns all prefixes in parallel

- Teacher forcing
- Faster training using causal mask

Masked self attention

Encoder Decoder Attention

Target attends to the source.

Q K V in Encoder Decoder Attention

- Q representation of all target words
- K, V representation of all source words
- New representation of each target word

$$r_t = \sum_{i=1}^{\text{source length}} w_{it} V_i$$

$$w_{it} \propto q_t \cdot k_i$$

Using the last decoder's last word representation,
we predict the next word

$$r_t \quad 1 \times d_{\text{model}} \quad W_{\text{out}} \quad Z \times V_{\text{decoder}}$$

softmax(z) gives us the probability distribution

- At training time, the whole sequence is predicted in one go for efficiency.

Decoder Parameter Count
